Seismic Base Isolation in Reinforced Concrete Structures

Dia Eddin Nassani¹, Mustafa Wassef Abdulmajeed¹

¹Department of Civil Engineering, Hasan Kalyoncu University, Gaziantep, Turkey

Abstract: Seismic hazards are a major concern in many populous regions of the world. Performance-based seismic design has brought about new technological advances and introduced an innovative approach to constructing seismic-resistant buildings. Base isolation systems are increasingly utilized methods of advanced seismic resistance, and the effects of these systems on the seismic responses of structures are studied in this paper. In order to verify the effect of base isolation system, two different structures are presented (symmetrical and non-symmetrical school buildings) in which the seismic responses of the 'fixed-base' and 'base-isolated' conditions have been compared using SAP2000 (a well-known computer program). The high damping rubber isolation system has been used and devices have been installed at the foundation level. Time history analysis has been performed on three earthquakes: El Centro, Loma and Coyote. Comparing the results of the base isolated condition with those obtained from the fixed-base condition has shown that the base isolation system reduces the base shear force and story drifts, whilst also increasing the displacement.

Keywords: Base isolation, Rubber, Earthquake, Drift, Base shear

1. INTRODUCTION

Earthquakes are one of nature’s greatest hazards; throughout historic time they have caused significant loss of life and severe damage to property, especially to man-made structures. On the other hand, earthquakes provide architects and engineers with a number of important design criteria foreign to the normal design process. From well established procedures reviewed by many researchers, seismic isolation may be used to provide an effective solution for a wide range of seismic design problems. The application of the base isolation techniques to protect structures against damage from earthquake attacks has been considered as one of the most effective approaches and has gained increasing acceptance during the last two decades. This is because base isolation limits the effects of the earthquake attack, a flexible base largely decoupling the structure from the ground motion, and the structural response accelerations are usually less than the ground acceleration [1].

Many comparative studies have revealed that the responses of the isolated structure are significantly smaller than the fixed base structure [2], [3], [4], [5], and [6]. Most of these studies compared the seismic demands (e.g. inter story drift, floor acceleration and base shear) for the two types of building structures, but only a limited number of studies investigated the responses of the isolated structure using high damping rubber (HDR) isolation with detailed procedures of the design of HDR. Skinner et al. [7] indicated that a base isolator with hysteretic force-displacement characteristics can provide the desired properties of isolator flexibility, high damping and force limitation under horizontal earthquake loads, together with high stiffness under smaller horizontal loads to limit wind-induced motions.

Kelly [8] gave a brief introduction to the response mechanisms of base isolated buildings through two degrees of freedom linear system. The effectiveness of the isolation system to mitigate the seismic response is through its ability to shift the fundamental frequency of the system out of the range of frequencies where the earthquake is strongest. Also, Skinner et al. [7] demonstrated that the most important feature of seismic isolation is that its increased flexibility increases the natural period of the structure. Because the period is increased beyond that of the earthquake, resonance is avoided and the seismic acceleration response is reduced.

Han et al. [9] studied the seismic risk analysis for an old non-ductile RC frame building before and after retrofit with base isolation with LRBs. They found that that the viscous damping, concrete compressive strength, steel yield stress and the beam–column joint parameter that defining the elastic range of the joint has the most impact on the structural seismic demand for the un-retrofitted building;
for the isolated buildings the temperature also have significant effects on the seismic demand. Base isolation was found to be effective in reducing seismic risk for higher damage levels.

Acar [1] studied the effect of HDR isolation on the seismic responses of different structures using IBC2000 and FEMA design codes and concluded that the site condition where earthquake data is recorded has a great influence on the design parameters of the structure. That is as the soil becomes softer, the response of the structure increases. Therefore the selected ground motion data must have been recorded on similar soil condition with the site where the structure is located.

In this paper, the effect of base isolation system on seismic responses of structures is studied. Two different structures are presented (regular and irregular 5-storey school buildings) in which the seismic responses of the fixed-base condition and HDR isolation condition have been compared using the well known computer program SAP2000 [10]. Time history analysis is performed using three earthquakes; El centro, Loma and Coyote.

2. **TYPES OF BASE ISOLATORS**

An easy way to comply with the paper formatting requirements of IJEERT is to use this document as a template and simply type your text into it.

The successful seismic isolation of a particular structure depends on the appropriate choice of the base isolation devices. The basic features of an isolation system are identified as:

- An increased flexibility so that the natural period of the structure is increased sufficiently to shift the frequency of the structure out of the range of dominant frequency of earthquake.
- A capacity for dissipating earthquake energy for resisting excessive horizontal displacement at the base of the building.

It is also necessary to provide an adequate seismic gap (between the structure and the surrounding foundations) which can accommodate the isolator displacements.

Many different forms of practical base isolation systems have been developed to provide seismic protection for buildings, including laminated elastomeric rubber bearings, lead rubber bearings, high damping rubber bearing, and friction pendulum sliding bearing [11].

2.1. **Laminated Rubber (Elastomeric) Bearing**

Laminated rubber bearings are constructed of alternating rubber layers bonded to intermediate reinforcing plates that are typically steel as illustrated by the schematic of a deformed bearing shown in Fig1. The total thickness of rubber provides the low horizontal stiffness need to achieve the period shift whereas the spacing of the steel shim plates controls the vertical stiffness of the bearing for a given shear modulus and bonded rubber area [12].

![Fig1. Schematic of a laminated rubber bearing in the laterally deformed configuration](image-url)
2.2. High Damping Rubber (HDR) Bearing

The energy dissipation in high-damping rubber bearings is achieved by special compounding of the elastomeric. Damping ratios will generally range between 8% and 20% of critical. The shear modulus of high-damping elastomeric generally ranges between 0.34 MPa and 1.40 MPa. The material is nonlinear at shear strains less than 20% and characterized by higher stiffness and damping, which minimizes the response under wind load and low-level seismic load. Over the range of 20-120% shear strain, the modulus is low and constant. At large shear strains, the modulus and energy dissipation increase. This increase in stiffness and damping at large strains can be exploited to produce a system that is stiff for small input, is fairly linear and flexible at design level input, and can limit displacements under unanticipated input levels that exceed design levels [12]. HDR bearing is shown in Fig2.

![Fig2. High damping rubber bearing [13]](image1)

2.3. Lead Rubber Bearing (LRB)

Lead-plug bearings are generally constructed with low-damping elastomers and lead cores with diameters ranging 15% to 33% of the bonded diameter of the bearing as shown in Fig3. Laminated-rubber bearings are able to supply the required displacements for seismic isolation [12]. By combining them with a lead-plug insert which provides hysteretic energy dissipation, the damping required for a successful seismic isolation system can be incorporated in a single compact component.

![Fig3. Lead Rubber Bearing [13]](image2)
2.4. Friction Pendulum Sliding (FPS) Bearing

The concept of sliding bearings is also combined with the concept of a pendulum type response, obtaining a conceptually interesting seismic isolation system known as a friction pendulum system (FPS) [14] as shown in Fig. 4. In FPS, the isolation is achieved by means of an articulated slider on spherical, concave chrome surface.

![Friction pendulum system](image)

Fig4. Friction pendulum system [13]

3. DETAILS OF MODEL

In this research, the evaluation and comparison of seismic responses of base isolated structures with those of fixed base are performed. Two different structures are presented in this study, the first structure is regular and the second is irregular.

3.1. The Regular Structure

The symmetric structure consist of 5-storey reinforced concrete school building with regular plan. The school plan and elevation are shown in Fig. 5, Fig. 6 and Fig. 7. The slab thickness is 16 cm, the column section 55x55 cm and beam section is 30 x 70 cm.

![Plan view of the regular structure](image)

Fig5. Plan view of the regular structure
For isolating the structure, 24 units (HDR) are used. The basic structural data to be used for the design is as follows:

TD = 2.10 sec. (Target period for ‘Design Level’ earthquake)

TM = 2.50 sec. (Target period for ‘Max. Capable Level’ earthquake)

R = 1.00 (Seismic load reduction factor)

G = 550 kN/m² (shear modulus of HDR)

G = 700 kN/m² (small shear strain)

K = 2,000,000 kN/m² (Bulk modulus)

β = 15% (Damping ratio of isolator)

WT = 14068 kN (Total weight of the structure)

γmax = 150%
3.1.1. Lateral Stiffness of Base Isolators

By using the equation for ‘Design Level Earthquake’ [15]:

\[ T_D = 2\pi \sqrt[4]{\frac{W}{K_s g}} \]  
\[ 2.1 = 2\pi \sqrt[4]{\frac{14068}{K_{total} \times 9.81}} \rightarrow K_{total} = 11697 \text{kN/m} \]  
\[ K_s = \frac{11697}{24} = 487 \text{kN/m} \text{ (for one bearing)} \]

For ‘Maximum Capable Earthquake Level’:

\[ 2.5 = 2\pi \sqrt[4]{\frac{14068}{K_{total} \times 9.81}} \rightarrow K_{total} = 6290 \text{kN/m} \]
\[ K_M = \frac{6290}{24} = 262 \text{kN/m} \text{ (for one bearing)} \]

Where \( k_D \) and \( k_M \) are the minimum lateral stiffness of base isolation bearings corresponding to the ‘design earthquake’ and ‘maximum capable earthquake’, respectively.

3.1.2. Estimation of Lateral Displacements

From the equation [15]:

\[ D_B = \left( \frac{g}{4\pi^2} \right) \frac{S_D T_D}{B_D} \]  
\[ D_D = \left( \frac{9.81}{4\pi^2} \right) \frac{0.65 \times 2.5}{1.38} = 0.24 \]
\[ D_M = \left( \frac{9.81}{4\pi^2} \right) \frac{0.65 \times 2.5}{1.38} = 0.29 \]

where \( DD \) and \( DM \) are the displacements of the isolation system corresponding to the ‘design earthquake’ and ‘max. capable earthquake’, respectively. The damping reduction factor \( B = 1.38 \) is obtained from Equation [15].

3.1.3. Estimation of Disc Dimensions

Thickness of the disc can be calculated by,

\[ t_r = \frac{D_B}{\gamma_{max}} = \frac{0.24}{1.5} = 0.16 \text{m} \]

Take \( tr = 20 \text{ cm} \)

Disc diameter, \( \Phi \) is estimated by using the equation [12]:

\[ A = \frac{487 \times 0.2}{550} = 0.177 \text{ m}^2 \rightarrow \phi = \sqrt{\frac{4A}{\pi}} = 0.475 \text{ m} \]

Take \( \phi = 50 \text{ cm} \)

3.1.4. Bearing Detail

For compressive stresses under vertical loads, the isolators undergo relatively smaller shear strain on older \( \gamma = 0.2 \) therefore \( G = 700 \text{ KN/m} \) should be used. Shape factor, \( S \), is selected as 8. The compression modulus, \( Ec \), from the equation [12]
\[ E_c = \left( \frac{1}{6GS^2} + \frac{1}{K} \right)^{-1} \]  

(4)

Where:

\( E_c \) : Compression Modulus, \( S \) : Shape Factor (5 < \( S \) < 30)
\( K \) : Bulk Modulus (1000MPa < \( K \) < 2500 MPa), \( G \) : Shear Modulus (0.5MPa < \( G \) < 2.5 MPa)

\[ E_c = \left( \frac{6 \times 700 \times 8^2 \times 2000000}{6 \times 700 \times 8^2 + 2000000} \right) = 236953kN/m^2 \]

where the total vertical stiffness is determined from the equation [12]:

\[ K_v = \frac{E_c A}{t_r} \]  

(5)

\[ K_v = \frac{236953 \times 24 \times 0.177}{0.2} = 503288kN/m \]

\[ K_v = \frac{503288}{24} = 209700kN/m \]  

(for one bearing)

\( S = \frac{\phi}{4t_0} \rightarrow t_0 = \frac{500}{4 \times 8} \approx 16mm \)

From the equation

\( n \times t_0 = 10 \times 16 = 160mm \) \((n = 10\text{ layers})\)

Consequently, the design of the bearing is completed as shown in Fig. 8. The end plates are 25mm thick, and the steel shims are 2mm each. The total height is:

\[ h = (2 \times 25) + (10 \times 16) + (9 \times 2) = 228mm \]

Steel shims will have a diameter \( \Phi_s = 490 \) mm, giving 5mm cover.

- Material and Structural Properties:
  - Weight per unit volume = 25 kN/m³
  - Modulus of elasticity, \( E_c = 24855500 \) kN/m²
  - Poisson’s ratio = 0.20
  - Shear modulus = 10356490 kN/m²
  - Co-efficient of thermal Expansion = 9.9E-06
Gravity loads on the structure include the self-weight of beams, columns, slabs. The self-weight of beams and columns (frame members) and slabs (area sections) is automatically considered by the program itself.

3.2. The Irregular Structure

The non-symmetric structure is 5-storey reinforced concrete school building with irregular plan. The school plan and elevation are shown in Fig. 9, Fig. 10 and Fig. 11.

The slab thickness is 16 cm, the column section 55x55 cm and beam section is 30 x 70 cm.

Fig 9. Plan view of the irregular structure

Fig 10. Sectional view of the irregular structure

Fig 11. 3D view of the non-symmetric building
4. ANALYSIS AND RESULTS

Time history analysis is carried out to find seismic responses of structures using SAP 2000 software [10]. For time history analysis, three different earthquakes have been used El centro, Loma and Coyote.

4.1. The Symmetrical Building

4.1.1. Scaling of the Results

The symmetrical building is analyzed with time history analysis and the results of the analysis are scaled according to IBC2006 [16]. The parameters needed for the calculation of scaling factors are given below. The damping coefficient, $B_D$, is taken as 1.38 in the analysis. The fixed based period, $T$, and isolated period, $T_D$, of the building are given in Table 1.

Table 1. Fixed and isolated periods of the building

| T (sec.) | 0.65 |
| TD (sec.) | 2.7 |

When IBC2006 is considered, the design displacement determined by time history analysis, $D_{analysis}$, must be greater than 90% of $D_{TD}$.

$$D_{TD} \geq D_o \left[ 1 + \gamma \left( \frac{12e}{b^2 + d^2} \right) \right]$$ (ASCE 7-05) (6)

Where:

d = Shortest plan dimension, b = Longest plan dimension

e = The actual eccentricity measured in plan between the center of mass of the structure and the center of stiffness of the isolation system, plus the accidental eccentricity taken as 5% of the longest plan dimension of the structure perpendicular to the direction of seismic loading under consideration.

On the other hand, the design base shear force on the structure above the isolation system must be greater than 60% of $V_S$.

$$V_S = \frac{K_s D_o}{R}$$ (ASCE 7-05) (7)

Otherwise, all response parameters, including component actions and deformations, must be adjusted proportionally upward. When the results of the analyses are examined, it is seen that the first scaling limit, $D_{analysis}> 90%$ of $D_{TD}$, is more critical than the second one and results in greater scaling factors. Therefore, it is used in the scaling factor calculations. Table 2 shows the calculations of scaling factor.

4.2. The Non-Symmetrical Building

4.2.1. Scaling of the Results

The non-symmetrical building is analyzed with time history analysis and the results of the analysis are scaled according to IBC2006 [16]. The parameters needed for the calculation of scaling factors are given below. The damping coefficient, $B_D$, is taken as 1.38 in the analysis. The fixed based period, $T$, and isolated period, $T_{D1}$, of the building are given in Table 6.

Table 6. Fixed and isolated periods of the building

When IBC2006 is considered, the design displacement determined by time history analysis, $D_{\text{analysis}}$, must be greater than 90% of $D_{TD1}$. On the other hand, the design base shear force on the structure above the isolation system must be greater than 60% of $V_S$.

Otherwise, all response parameters, including component actions and deformations, must be adjusted proportionally upward. When the results of the analyses are examined, it is seen that the first scaling limit, $D_{\text{analysis}} > 90\%$ of $D_{TD1}$, is more critical than the second one and results in greater scaling factors. Therefore, it is used in the scaling factor calculations. Table 7 shows the calculations of scaling factor.

Comparing the base shear force in the base-isolated condition with those obtained from the fixed-base condition for symmetrical building has shown in Figure 12 and Figure 13.

![Fig12. Base shear force in rubber isolation along x direction](image-url)
5. CONCLUSION

- The results of the study show that the response of the structure can be reduced by using base isolation.
- Comparing the results of the base-isolated condition with those obtained from the fixed-base condition has shown that the base isolation system reduces the base shear force and story drifts, whilst also increasing the displacement as the following:
  - The base shear in x-direction is equal to 3557 kN for the base-isolated condition while it is equal to 13940 kN in fixed-base condition for symmetric building.
  - The base shear in y-direction is equal to 3506 kN for the base-isolated condition while it is equal to 14393 kN in fixed-base condition for symmetric building.
  - The base moment in x-direction and y direction for the base-isolated condition is less than the moment for the fixed base condition.
  - The drift ratio is (0.0007) for the base-isolated condition while it is 0.003 for the fixed-base condition.
